

Document

Hiya I'm a VERY amature astronomer in Adelaide Australia, and today, I heard some very interesting and exciting news from a local program on TV. As I couldn't find anything on it on the news server, I have posted this. However, if it is old information, tell me, and ill sue the TV station for saying they are 'Up to date' ;-) (Also, my news server could be slow. . so . . .!!! I only caught the end of the article, so all the information on the topic is not known to me at the moment. The news is of a small 'psudo' planet outside the orbit of pluto found in a Hawiian obsevatory, supposably 'recently' - acording to the report. It was meant to be about 150miles in diamater, and a faily large distance from the plutos orbit. (it had a computer drawing, and the orbit distance from pluto was about the same as neptune to pluto when they are furthest apart. This is all I found out about it. OH it is called Karna. (un-officially). CAn anyone give any more information to me on it??? Thanx. Brendan Woithe swoithe@crackle.aelmg.adelaide.edu.au BTW - if this is old news, does anyone know a good lawyer. . . .8)
